About **Aegis AI**

Aegis AI is a revolutionary tool designed to bring accessibility, transparency, and trust to the world of blockchain technology. With the increasing use of smart contracts in various industries, the need for efficient and user-friendly auditing tools has never been more critical. Aegis AI is the solution that bridges the gap between complex smart contract code and non-technical users, making it easy for anyone to ensure the security and reliability of their digital assets and transactions.

- Run quick audits from dApp using AI
- Generate detailed audit reports
- Monitor of smart contracts and protocols in real time.
- Automated Penetration Testing.

Introduction

Aegis AI offers an advanced AI-driven solution for smart contract auditing, designed to enhance the security of blockchain contracts with ease. Our platform caters to users of all skill levels, enabling thorough vulnerability assessments without requiring extensive coding knowledge. This user-friendly tool simplifies the auditing process, efficiently detecting potential security risks and malicious code within smart contracts.

By addressing critical security concerns, Aegis AI plays a vital role in fostering trust and growth in blockchain technology. Our solution is integral to promoting wider adoption of smart contracts, ensuring their reliability and integrity across various blockchain applications.

Project Overview

Aegis
AI

Project Name	Chooky
Symbol	\$CHOO
Address	0x244748587F145c0571E92e85429D711d1B4Cc43a
Type	ERC-20
Decimals	18
Total Supply	21,000,000
Market Cap	4380957
Exchange Rate	0.208617
Holders	1,163

Social Media

Audit Summary

Version	Delivery Date	Changelog
1.0	January 12, 2024	Layout project Automated / Manual Security Testing Summary

Note

This Audit report consists of a security analysis of the Chooky smart contract.

Vulnerability and Risk Level

Risk assessment gauges the likelihood and impact of potential threats exploiting vulnerabilities. It is quantified using **CVSS version 3.0** standards, providing a clear metric for organizational or system security evaluation.

Severity Level	CVSS Score	Description	Recommended Action
Critical	9-10	Severe threat with potential for major losses or complete failure.	Immediate action required to mitigate and resolve.
High	7-8.9	Can seriously compromise functionality and security, allowing potential exploitation.	Address promptly to prevent exploitation.
Medium	4-6.9	Impact certain aspects, potentially leading to unintended behaviors.	Correct within a reasonable timeframe to maintain integrity.
Low	2-3.9	Less likely to significantly impact performance but should be addressed.	Consider remediation, may accept risk based on context.
Information	0-1.9	Highlights areas for improvement or optimization, no security risk.	Review for potential enhancements, no immediate action.

Auditing Strategy and Techniques

In our review process, we leverage advanced, finetuned Large Language Models (LLMs) alongside sophisticated LLM agent mechanisms. This approach ensures comprehensive examination of the smart contract repository, targeting security vulnerabilities, code integrity, and adherence to the latest standards and best practices.

Our review blends the precision of machine learning models with human oversight. The finetuned LLMs efficiently parse and analyze every file, providing in-depth insights and faster results, which are then meticulously validated by our team of experts for accuracy and relevance.

Methodology

The audit of the smart contract Chooky was conducted using a systematic and risk-based approach. Emphasis was placed on essential aspects such as security, code quality, compliance, gas efficiency, and overall functionality.

Security Assessment

Our approach integrates advanced AI-driven techniques, primarily leveraging Large Language Models (LLMs) and GPT agents. This blend of AI tools provides an in-depth analysis, identifying and evaluating potential security vulnerabilities. Alongside this, we conduct targeted manual reviews to validate and contextualize the AI-generated insights, ensuring comprehensive and accurate security assessments.

Code Quality Evaluation:

LLMs played a key role in examining the code's quality, focusing on readability and maintainability. The AI analysis, combined with our expert review, ensured compliance with smart contract development standards.

Compliance Review:

Our audit included an LLM-assisted compliance check against industry standards like ERC-20 and ERC-721. This process pinpointed deviations, providing a basis for our detailed compliance recommendations.

Gas Efficiency Analysis:

AI tools evaluated the contract's gas consumption, offering insights into its execution efficiency. These findings were enhanced by expert analysis to suggest practical optimization strategies.

Functionality and Logic Verification:

The audit applied LLMs to validate the contract's functionality and logic, ensuring its operations matched the intended design. This automated check was complemented by thorough manual testing.

Overall Security

Honeypot

Honeypots are smart contracts that appear to have an obvious flaw in their design, which allows an arbitrary user to drain ether (Ethereum's cryptocurrency) from the contract, given that the user transfers a priori a certain amount of ether to the contract.

Is it a honeypot?		✓ The contract is not a Honey Pot	
Description		Owner cannot drain your wallet through honeypot	

Antiwhale

Certain features adopted to prevent large holders (aka whales) from exerting excessive influence or engaging in manipulative behaviors within the token ecosystem. Some examples are setting maximum transaction limits, imposing penalties for transactions exceeding some specific threshold, imposing a more equitable distribution of tokens

Can whales dump?		✓ The contract is Anti Whale	
Description		Whales can't dump	

Listing

Listings on multiple decentralized exchanges (DEX) with good amount of liquidity is a good sign

Is it on a dex?		✓ The contract is listed	
Description		You can swap tokens on dex	

Opensource

Open source contract is contract with source code that anyone can inspect, modify, and enhance.

Is code available?		✓ The contract is Open Source	
Description		Contract code can be reviewed and audited by anyone	

Proxy

Proxy contract is a contract that delegates calls to another contract. It is a contract that has a fallback function that calls another contract. If the proxy contract is well-designed, secure, and serves a legitimate purpose (such as upgradability or modularity), it may not raise concerns. However, if the proxy introduces vulnerabilities, lacks transparency, or is used in a way that compromises the security of the token, it could be flagged during a thorough audit.

Is it a proxy?

✓ The contract is not a Proxy contract

Description

This is a full contract

Ownership

Is ownership renounced?	
✗ Contract has an owner	
Description	The owner has not renounced the ownership that means that the owner retains control over the contract's operations, including the ability to execute functions that may impact the contract's users or stakeholders. This can lead to potential issues.
Comments	Centralization The owner has significant control over contract's operations.

Note

If the contract is not deployed then we would consider the ownership to be not renounced. Moreover, if there are no ownership functionalities, ownership is automatically considered renounced.

Ownership Privileges

These functions can be dangerous. Please note that abuse can lead to financial loss. We have a guide where you can learn more about these Functions.

Minting Privileges

Minting is the process of creating new tokens. This is usually done by the contract owner, and the newly minted tokens are added to the owner's balance. Minting is usually done to increase the total supply of a cryptocurrency or token.

Can mint new tokens?

✓ The owner cannot mint new tokens

Description

The owner cannot mint new tokens

Modify Balance

If the owner can modify the token holders balance, it can be used to steal tokens from the token holders. The owner can also burn tokens without any allowance.

Can modify
balances?

✓ The owner cannot modify token balance

Description

The owner is not able to modify
token balance without any
allowance

Blacklist addresses

Blacklisting addresses in smart contracts is the process of adding a certain address to a blacklist, effectively preventing them from accessing or participating in certain functionalities or transactions within the contract. This can be useful in preventing fraudulent or malicious activities, such as hacking attempts or money laundering.

Can blacklist
addresses?

 Owner can blacklist addresses

Description

The contract owner can blacklist
addresses if they want

Fees and tax

In some smart contracts, the owner or creator of the contract can set fees for certain actions or operations within the contract. These fees can be used to cover the cost of running the contract, such as paying for gas fees or compensating the contract's owner for their time and effort in developing and maintaining the contract.

Is there a tax?	
Description	 Contract takes a tax
	There is a tax to the contract owner when you sell the token Tax on sell: 5%

Self Destruct

In a smart contract, the selfdestruct feature refers to a specific function that, when executed, destroys the contract and removes it from the blockchain. This action renders the contract inoperative and ends all its functions. When a contract is self-destructed, any remaining balance in the contract is sent to a designated address, and the contract's code and storage are removed from the state of the blockchain.

Can self
destruct?

✓ Contract cannot self destruct

Description

The smart contract does not include a self-destruct feature.

External / Public functions

External/public functions are functions that can be called from outside of a contract, i.e., they can be accessed by other contracts or external accounts on the blockchain. These functions are specified using the function declaration's external or public visibility modifier.

State variables

State variables are variables that are stored on the blockchain as part of the contract's state. They are declared at the contract level and can be accessed and modified by any function within the contract. State variables can be denoted with a visibility modifier, such as public, private, or internal, which determines the access level of the variable.

Components

External	Internal	Private	Pure
11	13	0	0

Exposed Functions

This section lists functions that are explicitly declared public or payable. Please note that getter methods for public state variables are not included.

Public	Payable
11	0

External	Internal	Private	Pure	View
11	13	0	0	20

State Variables

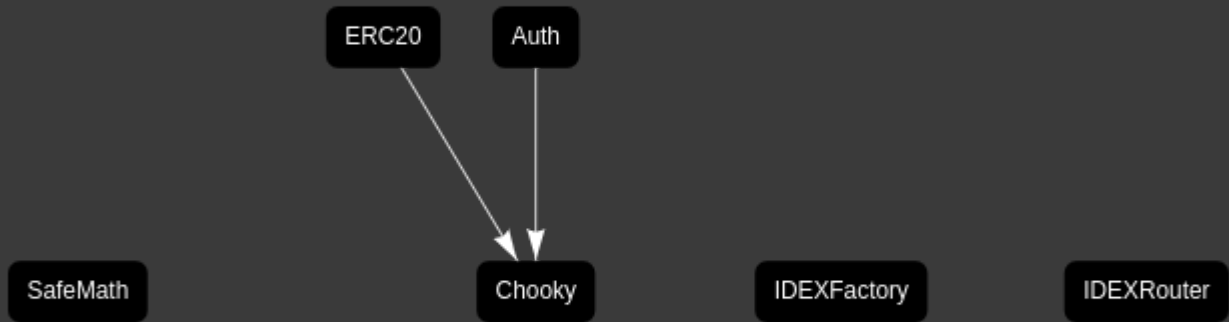

Total	Public
65	20

Capabilities

Aegis Version observed	Transfers ETH	Can Receive Funds	Uses Assembly	Delegate Call
$\geq 0.6.0$ $< 0.9.0$	Yes	Yes	Yes	Yes

Inheritance Graph

Centralization Privilege

Centralization can arise when one or more parties have privileged access or control over the contract's functionality, data, or decision-making. This can occur, for example, if the contract is controlled by a single entity or if certain participants have special permissions or abilities that others do not. In the project, there are authorities that have access to the following functions:

Contract	Privileges
SafeMath	N/A
ERC20	transfer, approve, transferFrom
Auth	authorize, unauthorize, transferOwnership
IDEXFactory	createPair
IDEXRouter	addLiquidity, swapExactTokensForTokensSupportingFeeOnTransferTokens, swapExactTokensForETHSupportingFeeOnTransferTokens
Chooky	approve, approveMax, transfer, transferFrom, clearStuckBalance, rescueERC20, tradingStatus, setMaxWallet, setBL, updateF, setIsFeeExempt, setIsMaxWalletExempt, setBuyFee, setSellFee, setTransferFee, setMarketingFeeReceivers, setSwapBackSettings, setAutomatedMarketMakerPair

Audit Results**#AEG-1 Ownership takeover**

FILE	Severity
Chooky.sol	INFO

Description - The transferOwnership function allows the current owner to transfer ownership to any address, which could be exploited if the owner's account is compromised. There is no check to prevent the owner from transferring ownership to an attacker's address, or even to the zero address, which would result in loss of control over the contract.

#AEG-2 Reentrancy attack

FILE	Severity
Chooky.sol	LOW

Description - The swapBack function can be potentially re-entered by a callback from the router.swapExactTokensForETHSupportingFeeOnTransferTokens call. Even though there is a swapping modifier used to prevent reentrancy, it is set to true before the external call and set to false after. Therefore, if the called contract is malicious and can call back into swapBack or other functions in this contract, it can lead to unexpected behavior, including draining funds or causing logic errors.

Audit Results**#AEG-3 Centralization risk**

FILE	Severity
Chooky.sol	INFO

Description - The `setAutomatedMarketMakerPair` function allows the owner to add or remove pairs from the `_markerPairs` array, which is used to determine if an address is an automated market maker pair. This centralizes control over the contract's interaction with market makers, which could be abused by the owner to manipulate the market or restrict trading.

Files Overview

The Chooky team provided us with the files that should be tested in the security assessment. This audit covered the following files listed below with an SHA-1 Hash.

File Name

Chooky.sol

Imported Packages

Used code from other Frameworks/Smart Contracts (direct imports).

Note for Investors:

We only audited a token contract for Chooky. However, If the project has other contracts (for example, a Presale, staking contract etc), and they were not provided to us in the audit scope, then we cannot comment on its security and are not responsible for it in any way.

No external libraries used.

Source

language: solidity

version: 0.8.18+commit.87f61d96

verified at: December 18, 2023 at 06:09:43 PM (UTC+0)

Conclusion

The audit of Chooky (\$CHOO), a cryptocurrency token, presented a solid performance and conclusion. The token showcases promising uptake with over 1163 holders, a feature that signifies good adoption. Notably, the token also boasts more than 2 Liquidity Provider (LP) holders, a positive aspect that contributes to the token's health. Chooky (\$CHOO) stands firm in its scarcity commitment as it is non-mintable, ensuring no further manufacturing of the token. This policy, combined with the antiwhale measures in place, makes it apparent that the platform is committed to preventing market manipulation and maintaining a fair and stable trading environment. The sell tax is at 5%, a tad on the higher side, but interestingly, there is no buy tax, which is welcoming news for investors planning on buying. Security is seemingly robust for Chooky (\$CHOO) as it sailed through the audit without any high or medium severity issues, implying a strong security posture. That said, the audit did unveil one low-severity issue. While this isn't typically cause for alarm, it is optimal for this matter to be addressed in due time to ensure the platform remains risk-free. However, a word of caution for users: there is a blacklisting function. Though this is to be expected and isn't out of the ordinary, it's something potential investors should be aware of. Lastly, the token is listed on a decentralized exchange (dex), which is the standard in the crypto world. In conclusion, Chooky (\$CHOO) fared well in the audit. With no significant vulnerabilities discovered, timely adoption of the suggested improvements would render Chooky (\$CHOO) as a potentially secure and rewarding token for crypto enthusiasts.

Conclusion Overview

Overview	Notes	Result
Honeypot	The contract owner can drain the funds from the contract	✓ False
Anti whale check	Features preventing whales from manipulating the Token	✓ True
Opensource	The code of the contract is public	✓ True
Ownership renounced	Contract owner has renounced ownership	✗ False
Buy tax	Fees incurred when buying the token	✓
Sell tax	Fees incurred when selling the token	✓
High Severity Issues	Number of High severity issues	0
Medium Severity Issues	Number of Medium severity issues	0
Mintable	Can mint new tokens	✓ False
Blacklist	Owner can blacklist users	✗ True
Holders	Total wallets holding the token	1163
LP holder	Number of liquidity providers	2

Glossary

1. Honeypot:

A honeypot refers to a deceptive contract that lures investors by appearing lucrative or profitable. These contracts typically allow users to easily purchase tokens, but selling them is restricted or impossible. This tactic is used to trap funds, misleading investors who are unable to withdraw their investments.

2. Blacklist:

A blacklist refers to a mechanism that enables the contract owner to restrict certain addresses from buying or selling the token. This feature is often implemented to block suspected bots or malicious actors from manipulating the token's market. However, it can also be used to unfairly prevent legitimate users from selling their tokens, posing a risk to token holder rights.

3. Ownership Privileges:

Ownership privileges refer to the exclusive rights and controls a contract owner possesses. These can include altering critical contract parameters, managing listings on decentralized exchanges, and updating contract logic. While revoking ownership can enhance trust among users by making the contract immutable, maintaining ownership is crucial for larger projects that require ongoing management and adaptability to evolving blockchain ecosystems.

4. Automated Penetration Testing:

Automated Penetration Testing is a cybersecurity practice that employs automated tools and technologies to identify and exploit vulnerabilities in computer systems, networks, or applications. It aims to simulate potential cyberattacks to assess the security posture and discover weaknesses in order to enhance overall defense against malicious activities.

5. LLM:

A large language model (LLM) is a type of artificial intelligence (AI) algorithm that uses deep learning techniques and massively large data sets to understand, summarize, generate and predict new content.

6. CVSS:

CVSS stands for the Common Vulnerability Scoring System. It's a way to evaluate and rank reported vulnerabilities in a standardized and repeatable way.

7. EOA:

Externally Owned Accounts (EOAs) are the most common type of blockchain account that gives us direct control. These accounts are created using private keys. The associated key gives you a unique signature and access to the blockchain. You can use it to send and receive transactions and interact with applications.
